WATER LEVEL MONITORING SYSTEM

Problem Statement

Water wastage and the lack of proper water-level monitoring are common problems in homes, colleges, and industries. Manually checking the water level in a tank can be difficult and time-consuming. Therefore, a simple and cost-effective system is needed to monitor the water level and display the status clearly. This project uses an Arduino Uno and a water-level sensor to detect the water level and display the sensor reading and water status on an LCD.

Abstract

The **Water Level Monitoring System Using Arduino Uno** is designed to monitor water level using a water-level sensor module and a 16×2 LCD display. The sensor detects water and produces an analog signal. The Arduino Uno reads this signal through its analog input pin and classifies the water level as Empty, Low, Medium, or High based on predefined threshold values. The LCD displays the sensor reading and the corresponding water-level status in real time. This system is simple, economical, and easy to implement. It helps users monitor water availability and can be further enhanced with Wi-Fi connectivity for remote monitoring through an IoT platform.
